3.

The figure below shows a Recurrent Neural Network (RNN) with one input unit  $\boldsymbol{x}$ , one logistic hidden unit  $\boldsymbol{h}$ , and one linear output unit

#### Lecture 7 Quiz

Quiz, 6 questions

 $\emph{\textbf{y}}$ . The RNN is unrolled in time for T=0,1, and 2.

The network parameters are:  $W_{xh}=0.5$  ,  $W_{hh}=-1.0$  ,  $W_{hy}=-0.7$  ,  $h_{bias}=-1.0$ , and  $y_{bias}=0.0$ . Remember,  $\sigma(k)=rac{1}{1+\exp(-k)}$ .

If the input x takes the values 9,4,-2 at time steps 0,1,2 respectively, what is the value of the output y at T=1? Give your answer to at least two digits after the decimal point.

4.

The figure below shows a Recurrent Neural Network (RNN) with one input unit  $\boldsymbol{x}$ , one logistic hidden unit  $\boldsymbol{h}$ , and one linear output unit

 $\boldsymbol{y}$ . The RNN is unrolled in time for T=0,1, and 2.

Quiz, 6 questions

The network parameters are:  $W_{xh}=-0.1$  ,  $W_{hh}=0.5$  ,  $W_{hy}=0.25$  ,  $h_{
m bias}=0.4$ , and  $y_{\rm bias}=0.0$ .

If the input x takes the values 18, 9, -8 at time steps 0, 1, 2 respectively, the hidden unit values will be 0.2, 0.4, 0.8 and the output unit values will be 0.05, 0.1, 0.2 (you can check these values as an exercise).

A variable z is defined as the total input to the hidden unit before the logistic nonlinearity.

If we are using the squared loss, with targets  $t_0, t_1, t_2$ , then the sequence of calculations required to compute the total error  $m{E}$  is as follows:

$$egin{array}{lll} z_0 = & W_{xh} x_0 + h_{ ext{bias}} & z_1 = & W_{xh} x_1 + W_{hh} h_0 + h_{ ext{bias}} & z_2 = & W_{xh} x_2 + W_{hh} h_1 + h_{ ext{bias}} \ h_0 = & \sigma(z_0) & h_1 = & \sigma(z_1) & h_2 = & \sigma(z_2) \ y_0 = & W_{hy} h_0 + y_{ ext{bias}} & y_1 = & W_{hy} h_1 + y_{ ext{bias}} & y_2 = & W_{hy} h_2 + y_{ ext{bias}} \ E_0 = & \frac{1}{2} (t_0 - y_0)^2 & E_1 = & \frac{1}{2} (t_1 - y_1)^2 & E_2 = & \frac{1}{2} (t_2 - y_2)^2 \ E = & E_0 + E_1 + E_2 & E_3 = & E_3 + E_4 + E_4 \end{array}$$

If the target output values are  $t_0=0.1, t_1=-0.1, t_2=-0.2$  and the squared error loss is used, what is the value of the error derivative just before the hidden unit nonlinearity at T=2 (i.e.  $\frac{\partial E}{\partial z_2}$ )? Write your answer up to at least the fourth decimal place.

point

5.

Consider a Recurrent Neural Network with one input unit, one logistic hidden unit, and one linear output unit. This RNN is for modeling sequences of

length 4 only, and the output unit exists only at the last time step, i.e. T=3. This diagram shows the RNN unrolled in time:

Suppose that the model has learned the following parameter values:

- $w_{xh} = 1$
- $w_{hh} = -2$
- $w_{hy} = 1$
- · All biases are 0

For one specific training case, the input is 1 at T=0 and 0 at T=1, T=2, and T=3. The target output (at T=3) is 0.5, and we're using the squared error

loss function.

We're interested in the gradient for  $w_{xh}$ , i.e.  $\frac{\partial E}{\partial w_{xh}}$ . Because it's only at T=0 that the input is not zero, and it's only at T=3 that there's an output, the

error needs to be backpropagated from T=3 to T=0, and that's the kind of situations where RNN's often get either vanishing gradients or exploding

gradients. Which of those two occurs in this situation?

You can either do the calculations, and find the answer that way, or you can find the answer with more thinking and less math, by thinking about the

slope  $\frac{\partial y}{\partial z}$  of the logistic function, and what role that plays in the backpropagation process.

Vanishing gradient

6.

Consider the following Recurrent Neural Network (RNN):

As you can see, the RNN has two input units, two hidden units, and one output unit.

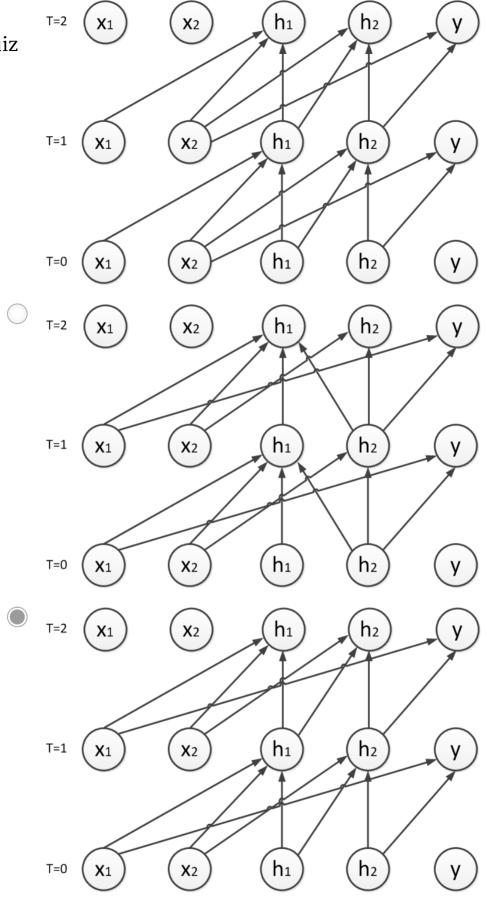

For this question, every arrow denotes the effect of a variable at time  $m{t}$  on a variable at time  $m{t}+m{1}$ .

Which feed forward Neural Network is equivalent to this network unrolled in time?
